---

Can you swear under oath that an unforeseen Michigan earthquake will not release the "non-hazardous" leachate [under 1100 plus pounds per square inch injection pressure] from being squeezed between rock channels allowing it to steadily rise to aquifer levels in your children's and grandchildren's lifetime? and is this really necessary, or are you and the EPA just accommodating the Landfill owners request to enhance his income? If the leachates are truly "non-hazardous" should you have any concern for your progeny's health or wellbeing in the first place? Perhaps placing the material near your city's wells would be considered safe? Until we have more long term reliable data with public education and acceptance, it seems the best position is one of caution and NO at this time.
